## Topic 7. Missing Values in Longitudinal Data

**Missing values** - One or more of the intended measurements from units within the study are not taken, are lost, or are unavailable.

e.g. 社会行落科学  
的问卷

**Classification of missing value mechanisms:**

实际看到      理看到未看到

Let  $Y^* = (Y^{(o)}, Y^{(m)})$  with  $Y^{(o)}$  denoting the measurements actually obtained and  $Y^{(m)}$  being the measurements which would have been available if they were not missing. Let  $R$  denote a set of indicator random variables, denoting which elements of the complete set of measurements fall into  $Y^{(o)}$  and which into  $Y^{(m)}$ .

**Missing value mechanism:**

- Completely random:  $R \perp (Y^{(o)}, Y^{(m)})$ . *Strongest assumption.*
- Random:  $R \perp Y^{(m)}$ . *[missing and random] 有某種結構. 较 mild.*
- Informative:  $R \not\perp Y^{(m)}$ .

怎麼辦?  $\hookrightarrow$  Imputation.  
插補法, How?

**Distinction between random and informative missing values:**

Let  $f(y^{(o)}, y^{(m)}, r)$  denote the probability density function of  $(Y^{(o)}, Y^{(m)}, R)$ . One has

$$f(y^{(o)}, y^{(m)}, r) = f_{Y^{(o)}, Y^{(m)}}(y^{(o)}, y^{(m)}) \underbrace{f_{R|Y^{(o)}, Y^{(m)}}(r | y^{(o)}, y^{(m)})}, \text{ which implies that}$$

$$f_{(Y^{(o)}, R)}(y^{(o)}, r) = \int f_{Y^{(o)}, Y^{(m)}}(y^{(o)}, y^{(m)}) f_{R|Y^{(o)}, Y^{(m)}}(r | y^{(o)}, y^{(m)}) dy^{(m)}.$$

1. Completely random:  $f_{Y^{(o)}, R}(y^{(o)}, r) = f_{Y^{(o)}}(y^{(o)}) f_R(r)$ . *missing 和 observed 独立.*

$$\begin{aligned} 2. \text{ Random: } f_{Y^{(o)}, R}(y^{(o)}, r) &= (\int f(y^{(o)}, y^{(m)}) dy^{(m)}) f_{R|Y^{(o)}}(r | y^{(o)}) \\ &= f_{Y^{(o)}}(y^{(o)}) f_{R|Y^{(o)}}(r | y^{(o)}). \end{aligned}$$

沒有說是獨立的。

**Remark.**

- If  $f_{R|Y^{(o)}}(r | y^{(o)})$  contains no information about the distribution of  $Y^{(o)}$ , it can be ignored for the purpose of making inferences about  $Y^{(o)}$ . Thus, both completely random and random missing mechanisms are sometimes referred to without distinction as ignorable.

## Selection model

- (b) If there are parameters common to  $f_{Y^{(o)}}(y^{(o)})$  and  $f_{R|Y^{(o)}}(r|y^{(o)})$ , ignoring  $f(r|y^{(o)})$  will lead to a loss of efficiency.

- (c) In some cases, it might be more sensible to make the distribution of time to survival and the conditional distribution of  $Y^{(o)}$  given survival.

### Intermittent missing values and dropouts: (間接性的)

Consider a sequence of measurements  $Y_1, \dots, Y_n$ , missing values occur as dropouts if whenever  $Y_j$  is missing, so are  $Y_k$  for all  $k \geq j$ . Otherwise, the missing values are intermittent.

- When intermittent missing values arise through a known censoring mechanism, an EM-algorithm provides a possible framework.
- When intermittent missing values do not arise from censoring and missingness is unrelated to the measurement process, the resulting data can be analyzed by any method which can accommodate unbalanced data.
- Dropouts are frequently lost to any form of follow-up and arise directly or indirectly connected to the measurement process.
- When there is any relationship between the measurements, the interpretation of apparently simple trends in the mean response over time can be problematic.  
 $\Rightarrow$  biased estimate.

**Example:** Random dropouts (constant mean response): The empirical means might suggest a clearly increasing time-trend and the likelihood-based means is essentially constant.

**Explanation 1.** The likelihood-based analysis estimates the mean response which would have been observed if there were no dropouts, whereas the empirical means estimate the conditional mean response in the sub-population who have not dropped out by time  $t$ .

longitudinal data.

**Explanation 2.** The likelihood-based method recognizes the correlation in data and, in effect, imputes the missing values for a particular subject taking into account the same subject's observed values.

## Simple solutions and their limitations:

1. Last observation carried forward - Extrapolating the last observed measurement for the subject in question to the remainder of their intended time-sequence.

### Method:

- a. Estimate the time trend, say  $\hat{\mu}_i(t)$ , of the  $i$ th response at time  $t$ .
- b. Let  $y_{ij}$  be the last observation of the  $i$ th subject and  $r_{ij} = y_{ij} - \hat{\mu}(t_j)$ .
- c. Impute the missing values as  $\hat{y}_{ik} = \hat{\mu}(t_k) + r_{ij}$  for  $k > j$ . 假設其 error structure 同前.
2. Complete case analysis – Discarding all incomplete sequences.

### Limitations:

- a. The complete cases might not be assumed to be a random sample.
- b. The incomplete data provide additional information about the underlying measurement process conditional on completion if we are prepared to model the relationship between the measurement process and the dropout process.

### Testing for completely random dropouts:

Random sample 意味着  
隨著時間 drop out

**Property:** Let  $P_{ij}$  denote the probability that the  $i$ th unit drops out at time  $t_j$ ,  $j = 1, \dots, m$ .

Under the assumption of completely random dropouts, the  $P_{ij}$  may depend on time, treatment, or other explanatory variables but cannot depend on the observed measurements  $y_i = (y_{i1}, \dots, y_{im_i})$ .

### Testing method: 什麼 score?

- a. Choose the score functions  $h_k(y_1, \dots, y_k)$  so that extreme values constitute evidence against completely random dropouts. A sensible choice is  $h_k(y_1, \dots, y_k) = \sum_{j=1}^k \omega_j y_j$ .
- b. For each of  $k = 1, \dots, (m-1)$ , define  $R_k = \{i : m_i \geq k\}$  and  $r_k = \{i : m_i = k\}$ , and compute the set of scores  $h_{ik} = h_k(y_{i1}, \dots, y_{ik})$  for  $i \in R_k$ .
- c. If  $1 \leq \#(r_k) < \#(R_k)$ , test the hypothesis that the  $r_k$ 's scores so defined are a random sample from the “population” of  $R_k$ 's scores.

$R_k$  random sample

of  $R_k$ ?

process 的 conditional  
independent 的結構.

### Remark.

1. The implicit assumption that the separate  $p$ -values are mutually independent is valid precisely because once a unit drops out it never returns.

HW06. Q1.

2. A natural test statistic is  $\bar{h}_k = \frac{1}{\#(r_k)} \sum_{j \in r_k} h_{jk}$ . Under the assumption that dropouts occur completely at random,

$$\bar{h}_k \approx N(\bar{H}_k, \frac{\#(R_k) - \#(r_k)}{\#(r_k)(\#(R_k) - 1)} \sum_{j \in R_k} (h_{jk} - \bar{H}_k)^2), \quad \bar{H}_k = \frac{1}{\#(R_k)} \sum_{j \in R_k} h_{jk}.$$

- (\* ) When  $\#(R_k)$  or  $\#(r_k)$  is small, evaluate the complete randomization distribution of  $\bar{h}_k$  under the null hypothesis.

- Boostrapping* (\*) Alternative method is to re-compute  $(s-1)$  new  $\bar{h}_k$ 's based on a sample of size  $\#(r_k)$  without replacement from  $\{h_{ik} : i \in R_k\}$ . Let  $x$  denote the rank of the original  $\bar{h}_k$  among the recomputed values. The  $p = \frac{x}{s}$  is the  $p$ -value of the exact Monte Carlo test.

3. Final stage consists of analyzing the resulting set of  $p$ -values via

$$\begin{cases} \text{Empirical distribution of the } p\text{-values} \\ \text{Kolmogorov-Smirnov statistic } D_+ = \sup |F_n(p) - p| \end{cases}$$

### Generalized estimating equations under a random missing mechanism:

前提:  $t=j$  时看到  $t=j-1$  时看到 history  
 $P(R_{ij}=1 | R_{ij-1}=1, H_{im}) = P(R_{ij}=1 | R_{ij-1}=1, H_{ij})$  只和  $t=j$  的 history 有关  
 看到的

Basic GEE method when dropouts are completely random:  $P(R_{ii}=1 | H_{im}) = 1$ .

$$S_\beta(\beta, \alpha) = \sum_{i=1}^n \left( \frac{\partial \mu_i}{\partial \beta} \right)^T \text{Var}(Y_i)^{-1} (Y_i - \mu_i) = 0$$

$$P(R_{iz}=1 | R_{ii}=1, H_m) = P(R_{iz}=1 | R_{ii}=1, H_m) P(R_{ii}=1 | H_{im})$$

$$P_{ij} = P(R_{ii}=1 | H_{ii}) P(R_{iz}=1 | H_{iz}, R_{ii}=1) P(R_{iz}=1 | H_{iz}, R_{ij-1}=1) \dots P(R_{ij}=1 | H_{ij}, R_{ij-1}=1)$$

Let  $P_i = \text{diag}(P_{ij})$ ,  $\text{diag}(P_y) = \prod_{k=1}^j \lambda_{ik}$  with  $\lambda_{ij} = P(R_{ij}=1 | R_{ij-1}=1, H_{ij})$ ,  $i=1, \dots, n$ .

When  $P_i$ 's are themselves estimated from the data using an assumed random dropout model, the estimators of  $\beta$  obtained from the following extended estimating equation are consistent.

$$S_\beta^*(\beta, \alpha) = \sum_{i=1}^n \left( \frac{\partial \mu_i}{\partial \beta} \right)^T \text{Var}(Y_i)^{-1} P_i^{-1} (Y_i - \mu_i) = 0$$

### Informative Dropout -

Modeling the dropout process:  
真實的完整的  
觀測到

Let  $Y^* = (Y_1^*, \dots, Y_m^*)$  and  $Y = (Y_1, \dots, Y_m)$  denote separately the complete set of intended measurements and the observed measurements, respectively.

Drop-out time  $D$  obeys the relationship  $Y_j = \begin{cases} Y_j^* & : j < D \\ 0 & : j \geq D \end{cases}$ .  
沒有看到

Note that  $2 \leq D \leq m+1$  with  $D = m+1$  indicating that the subject has not dropped out.  
D.W 屬於 Truncation.

### Model Selection:

$P(Y^*, D) = P(Y^*)P(D|Y^*)$ : Dropouts are selected according to their measurement history.

Remark:

- (a) Dropouts are completely random if  $P(D|Y^*) = P(D)$ .
- (b) Dropouts are random if  $P(D|Y^*) = P(D|Y_1^*, \dots, Y_{D-1}^*)$ .

Let  $H_k = (Y_1, \dots, Y_{k-1})$ . history (概率上的 filtration) 看得到的資料

$f_k^*(y_k^* | H_k; \theta, \phi)$ : the conditional p.d.f. of  $y_k^*$  given  $H_k$ .  $H_k^*$  : 看得到

$f_k(y_k | H_k; \theta, \phi)$ : the conditional p.d.f. of  $y_k$  given  $H_k$ .

$$P_k(H_k, y_k^*; \beta) = P(D=k | H_k, y_k^*; \beta).$$

### Properties:

drop out,  $D=k$

$$(p1) P(Y_k = 0 | H_k, Y_{k-1} = 0) = 1. \quad P(Y_k = 0 | H_k, Y_{k-1} \neq 0) = \int P(D=k | H_k, y_k^*; \beta) f_k^*(y_k^* | H_k; \theta, \phi) dy_k^* ?$$

$$(p2) P(Y_k = 0 | H_k, Y_{k-1} \neq 0) = \int P(D=k | H_k, y_k^*; \beta) f_k^*(y_k^* | H_k; \theta, \phi) dy_k^*.$$

$$= \int P_k(H_k, y_k^*; \beta) f_k^*(y_k^* | H_k; \theta, \phi) dy_k^*. \quad \text{complete data history}$$

$$(p3) f_k(y_k | H_k; \theta, \phi) = (1 - P_k(H_k, y_k; \beta)) f_k^*(y_k^* | H_k; \theta, \phi) \text{ for } y_k \neq 0.$$

$$f_k(y_k | H_k; \theta, \phi) = P_k(H_k, y_k; \beta) I(y_k = 0) + (1 - P_k(H_k, y_k; \beta)) f_k^*(y_k^* | H_k; \theta, \phi) I(y_k \neq 0).$$

$$f_k(0 | H_k, y_{k-1} \neq 0)$$

Survival 的 cure. 考慮群體中,

Properties (p1)-(p3) determine the joint p.d.f. of a complete sequence  $Y$  as

$$f_Y(y) = f_1^*(y_1) \prod_{k=2}^m f_k(y_k | H_k) = f_{Y^*}(y) \prod_{k=2}^m (1 - P_k(H_k, y_k; \beta)).$$

- 見看得到 -

drop out  
的  
model

For an incomplete sequence  $Y = (Y_1, \dots, Y_{d-1}, 0, \dots, 0)$ ,

$$f_Y(y) = \{f_1^*(y_1) \prod_{k=1}^{d-1} f_k(y_k | H_k)\} P(Y_d = 0 | H_d, Y_{d-1} \neq 0)$$

$$= f_{Y^*, \dots, Y_{d-1}}^*(y_1^*, \dots, y_{d-1}^*) \prod_{k=2}^{d-1} (1 - P_k(H_k, y_k^*; \beta)) (\int P_d(H_d, y_d^*; \beta) f_d^*(y_d^* | H_d; \theta, \phi) dy_d^*).$$

complete cf random  
random

**Remark.** Under either CRD or RD,  $P_k(H_k, y_k^*; \beta)$  does not depend on  $y_k^*$ , it implies that  $P(Y_k = 0 | H_k, Y_{k-1} \neq 0) = p(H_k; \beta)$  and the likelihood separates into two components, one for  $(\theta, \phi)$  and one for  $\beta$ . Let  $y_i = (y_{i1}, \dots, y_{id_i-1})^T$ ,  $i = 1, \dots, n$ .

The log-likelihood function for  $(\theta, \phi, \beta)$  can be partitioned as

$$L(\theta, \phi, \beta) = L_1(\theta, \phi) + L_2(\beta) + L_3(\theta, \phi, \beta) \quad \text{with}$$

$$L_1(\theta, \phi) = \sum_{i=1}^n \ln f_{Y^*, \dots, Y_{d_i-1}}^*(y_1, \dots, y_{d_i-1}), \quad L_2(\beta) = \sum_{i=1}^n \sum_{k=2}^{d_i-1} \ln(1 - P_k(H_{ik}, y_{ik}; \beta)), \quad \text{and}$$

$$L_3(\theta, \phi, \beta) = \sum_{\{i: d_i \leq m\}} \ln P(D_i = d_i | H_{d_i}, y_{id_i-1} \neq 0).$$

**Remark.** 看到 incomplete

1. Under RD,  $L_3(\theta, \phi, \beta)$  depends only on  $\beta$  and can therefore be absorbed into  $L_2(\beta)$ . Hence, the dropouts only affect  $L_2(\beta)$  and are ignorable for likelihood-based inference about  $(\theta, \phi)$ .

Similarly,  $L_2(\beta)$  is the log-likelihood associated with the sub-model for  $D$  conditional on  $Y^*$ . It follows that the stochastic structure of the measurement process can be ignored for likelihood-based inference about  $\beta$ .

2. The general strategy for the informative dropout process is to model the relationship between an observed dropout event and an unobservable concomitant. Typically, it leads to poor identifiability of the model parameters and making it difficult or impossible to validate the assumed model from the observed data.

### Pattern mixture models –

Pattern mixture models, introduced by Little (1993), work with the factorization of the joint distribution of  $Y^*$  and  $D$  into the marginal distribution of  $D$  and the conditional distribution of  $Y^*$  given  $D$ , thus  $P(Y^*, D) = P(D) P(Y^* | D)$ . \*

**Rationale for pattern mixture model:** Each subject's dropout time is somehow predestined, and that the measurement process varies between dropout cohorts.

The arguments in favor of pattern mixture modeling are usually of a more pragmatic kind.

1. Classification of subjects according to their dropout time provides separate inspection of sub-groups.
2. Pattern mixture factorization brings out very clearly those aspects of the models, which are assumption driven rather than data driven.

$$f(y^* | D = d) = f(y_1^* | d)f(y_2^* | y_1^*, d)\cdots f(y_d^* | y_1^*, \dots, y_{d-1}^*, d)\cdots f(y_m^* | y_1^*, \dots, y_{m-1}^*, d)$$

Assumption: ( $d < m + 1$  and  $t \geq d$ )

Complete case missing ~~variable~~ <sup>value</sup> restrictions: (CCMV)

$$f(y_t^* | y_1^*, \dots, y_{t-1}^*, d) = f(y_t^* | y_1^*, \dots, y_{t-1}^*, m).$$

Available case missing value restrictions: (ACMV)

$$f(y_t^* | y_1^*, \dots, y_{t-1}^*, d) = f(y_t^* | y_1^*, \dots, y_{t-1}^*, D > t).$$

$$\text{Property 1: } f(y_t^* | y_1^*, \dots, y_{t-1}^*, d) = f(y_t^* | y_1^*, \dots, y_{t-1}^*).$$

Property 2: Missing at random (MAR):  $f(D = d | y_1, \dots, y_m) = f(D = d | y_1, \dots, y_{d-1})$   
ACMV.
